

$$\begin{array}{r} 25.1 \\ - 24.7 \\ \hline \end{array}$$

- (a): We are told that the test returns negative for 10% of sick students and 70% of healthy students; there are 100 students, 20 of which are sick and the remaining 80 are not. Then, 2 of the sick students return negative and 56 of the healthy students return negative. The probability of being a sick student given that the test result is negative is then:

$$\frac{2}{2+56} \cdot 100\% = 3.45\%$$

- (b): We are going to multiply the initial ratios of good:Bad by the chances of those emitting sparks:

$$90\% : 10\% \cdot 4\% : 12\% = 3.6\% : 1.2\%$$

$$= 36 : 12$$

Now that we have calculated the ratios of good:Bad widgets that spark, find the probability of getting a bad widget:

$$\frac{12}{36+12} = \frac{12}{48} = 25\%$$

- (c): The probability for n returns the percent chance of the outcome in question occurring, while the odds form returns a ~~ratio~~ ratio of the composition of the overlapping outcomes. We add the value of the numerator to the denominator, ~~for ex~~ to find the probability; given the ratio, ~~the pr~~

$$\left(\frac{Z}{K} \right)$$

the probability can be written as

$$\frac{Z}{K+Z}$$

Now we'd like to prove Bayes' rule, that

$$\frac{P(H_j)}{P(H_k)} \cdot \frac{P(e_0|H_j)}{P(e_0|H_k)} = \frac{P(H_j|e_0)}{P(H_k|e_0)}$$

We see by the definition of conditional probability that $P(X \cap Y) = P(Y) \cdot P(X|Y)$, thus

$$\dots = \frac{P(e_0 \cap H_j)}{P(e_0 \cap H_k)} \quad \text{where } \cap \text{ is the intersection of the prob.}$$

multiply this by $\frac{1/e_0}{1/e_0}$ and note that intersection is commutative

$$\dots = \frac{P(e_0 \cap H_j)/e_0}{P(e_0 \cap H_k)/e_0} = \frac{P(H_j \cap e_0)}{P(H_k \cap e_0)} \cdot \frac{1/e_0}{1/e_0} = \frac{P(H_j \cap e_0)/e_0}{P(H_k \cap e_0)/e_0}$$

Recall that $P(X \cap Y)/P(Y) = P(X|Y)$

$$\dots = \frac{P(H_j|e_0)}{P(H_k|e_0)}$$

(d): Each drawer has a 10% probability mass;

8 drawers \cdot 10% mass drawer⁻¹ + 20% dresser = 100%.

Since we have searched 6 drawers without finding the socks, then

$$2 \cdot 10\% + 20\% \text{ not in dresser} = 40\%$$

The chance of finding the socks in the next drawer is 1/4th of the remaining probability mass

$$\frac{10\%}{40\%} \cdot 100\% = 25\%$$

(e): Refer to GitHub.
